Family Planning is partially funded to provide our services. We are grateful for donations to help us to continue our work.

Contraception Your Choice

WOMEN

How pregnancy happens

In women, an egg is released from one of the two ovaries, about once a month. This is called ovulation. The egg travels down a fallopian tube.

It may then be fertilised by a man's sperm released when a couple have sexual intercourse. The mucus in the cervix (opening to the uterus) changes just before ovulation and becomes clear and stretchy. This allows sperm to swim through it more easily.

If fertilised, the egg continues down the fallopian tube and attaches to the wall of the uterus where it grows into a baby.

If the egg is not fertilised, the lining of the uterus is shed in the monthly period of bleeding.

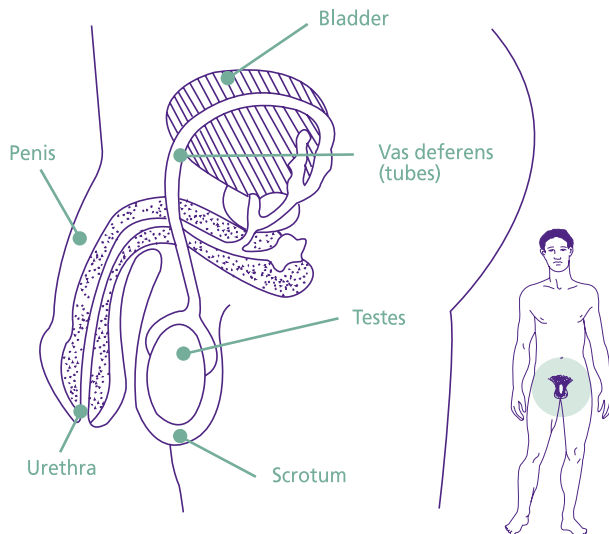

In men, sperm are produced in the testes (balls). Sperm travel up two tubes to mix with semen.

When a man ejaculates (cums) during sexual intercourse with a woman the semen goes into the vagina.

Within minutes the sperm travel through the cervix and uterus and into the fallopian tubes. If a sperm joins with an egg, the egg is fertilised.

Sperm can live up to seven days in a woman's body.

MEN

How to prevent pregnancy

Contraception prevents pregnancy by stopping sperm fertilising an egg.

There are a number of ways this can be done. Some methods are more reliable than others.

Your contraceptive needs may change over the years – what suits you at 20 may not be right at 40.

Some of these questions may help you decide which method to choose.

- How important is it that you don't get pregnant?
- Is this a suitable method for your
 - age
 - health
 - lifestyle?

Do you also need protection against sexually transmissible infections (STIs)?

Your nurse or doctor will discuss contraception with you and answer any questions you may have.

If you have a partner, it's a good idea for you both to think about the method which will suit you best.

Condoms help protect against sexually transmissible infections.
